## Paper 1: Retrieval Augmented Generation (RAG) for Evaluating Regulatory Compliance of Dru

### Bibliographic Information

- **Title**: Retrieval Augmented Generation (RAG) for Evaluating Regulatory Compliance of Drug Information and Clinical Trial Protocols
- **Authors**: Waikar S, Bhat AG, Ramanathan M
- **Journal**: CPT: Pharmacometrics & Systems Pharmacology, 2026
- **DOI**: https://ascpt.onlinelibrary.wiley.com/doi/10.1002/psp4.70201

### Quick Take

This pilot study demonstrates how Retrieval Augmented Generation (RAG) AI systems can automate the review of drug labels and clinical protocols against FDA guidance. It is essential reading for regulatory scientists and pharmacometricians interested in leveraging GenAI to streamline compliance checks and reduce manual review burden.

---

### Executive Summary

The authors developed and evaluated a Retrieval Augmented Generation (RAG) system designed to assess the regulatory compliance of drug package inserts and clinical trial protocols. By integrating Large Language Models (LLMs) with a vector database of specific FDA guidance documents, the system successfully evaluated five approved drugs and three withdrawn drugs, as well as a Phase 2a tuberculosis trial protocol. The study found that the RAG system provided more structured, actionable, and evidence-based critiques compared to standard GPT-4o interactions, particularly in identifying missing ethical considerations and specific compliance gaps. This work establishes a proof-of-concept for using AI 'co-pilots' in regulatory operations to enhance the efficiency and consistency of document review.

---

## ⚡ Methodological Snapshot

The authors constructed a RAG pipeline using the LangChain framework. The system ingests PDF documents (drug labels, protocols, and FDA guidance), creates vector embeddings, and utilizes a retrieval mechanism to feed relevant context into an LLM (ChatGPT/GPT-4o) alongside a persona-based prompt. The system was tested on two tasks: evaluating drug label sections (Indications, Specific Populations, Warnings) against 21 CFR/FDA guidance, and evaluating a clinical trial protocol against ICH E9 statistical principles. Performance was assessed using NLP metrics (ROUGE-L, METEOR) and a custom 'ClinPharm' metric evaluated by an LLM-as-a-judge (DeepEval framework).

---

## 🏗 Structural Model Breakdown

The 'model' is an AI architecture rather than a mathematical PK model. Structure: 1. Document Ingestion (PDFs of Label + Guidance). 2. Preprocessing & Chunking. 3. Embedding (Vector Store). 4. Retrieval (Top-k relevant chunks based on query). 5. Prompt Engineering (System Persona + Retrieved Context + User Query). 6. Generation (LLM Output). 7. Evaluation (DeepEval metrics).

---

### Detailed Methodological Analysis

#### Modeling Approach

Retrieval Augmented Generation (RAG) system implemented via LangChain and Streamlit. It utilizes vector embeddings for document indexing and semantic search to retrieve relevant regulatory guidance text before generating responses via ChatGPT/GPT-4o.

#### Data Sources

Approved Dataset: Package inserts for Adalimumab, Insulin Glargine, Atorvastatin, Sertraline, Alprazolam. Withdrawn Dataset: Valdecoxib, Rofecoxib, Troglitazone. Protocol: Phase 2a trial of Rifafour (NCT03557281). Regulatory Docs: 21 CFR, FDA Guidance (E9, E9(R1), Pediatric/Pregnancy guidance).

#### Estimation Methods

Performance quantification using ROUGE-L (longest common subsequence) and METEOR (semantic alignment) scores. Comparative analysis against direct GPT-4o queries without retrieval.

#### Model Evaluation

DeepEval framework used to calculate Answer Relevancy, Faithfulness, and a custom 'ClinPharm' metric (checking for contradictions to clinical pharmacology principles and penalizing omissions). Independent human verification by authors.

#### Covariate Analysis

The RAG system evaluated the clinical protocol's Statistical Analysis Plan (SAP) for covariate handling, specifically noting the omission of BMI as a covariate in the PK analysis section.

---

### Scientific Context & Motivation

Regulatory review of drug information and clinical protocols is a resource-intensive process requiring multidisciplinary expertise to ensure compliance with evolving FDA guidance. While standard LLMs offer summarization capabilities, they often hallucinate or lack domain-specific grounding. This study addresses the gap in applying RAG architectures—which retrieve and condition generation on specific source documents—to the specific task of regulatory compliance evaluation, moving beyond simple information extraction to decision-support and critique.

---

### Statistical Rigor Assessment

This was a pilot study with a small sample size (5 approved drugs, 1 protocol). The use of quantitative NLP metrics (ROUGE/METEOR) and a structured LLM-as-a-judge framework adds objectivity to the qualitative assessment. However, the sample size limits broad statistical inference about the tool's error rate across diverse therapeutic areas.

---

## 📊 Key Findings

The RAG system correctly extracted indications and warnings for all test drugs. Crucially, it identified compliance gaps, such as the absence of explicit ethical statements regarding pediatric assent in the Adalimumab label (required by guidance but often missing in older labels). In the protocol evaluation, the RAG system achieved 100% answer relevancy and 95% faithfulness. It correctly critiqued the Statistical Analysis Plan for lacking details on sample size re-estimation and dose escalation methods. Compared to GPT-4o, the RAG system was more critical and structured, whereas GPT-4o was more descriptive and lenient.

---

## 💡 Clinical & Regulatory Implications

RAG systems can serve as automated 'pre-flight' checks for regulatory submissions, allowing sponsors to identify compliance gaps in labels and protocols before FDA submission. This technology can assist medical writers and regulatory affairs professionals by ensuring consistency with the latest guidance documents, potentially reducing review cycles and regulatory queries.

---

### Strengths & Limitations

#### Strengths

- Novel application of RAG specifically for regulatory compliance checking
- Direct comparison between RAG and standard GPT-4o
- Integration of specific, complex FDA guidance documents (e.g., ICH E9)
- Use of 'LLM-as-a-judge' (DeepEval) for scalable evaluation

#### Limitations (Acknowledged by Authors)

- Small sample size of drugs and protocols
- Inability to process information in tables and graphs (multimodality issues)
- Limited to FDA guidance (did not include EMA/PMDA specifics unless prompted)

#### Limitations (Expert Review)

- The 'ClinPharm' metric is custom-defined and requires further validation
- Reliance on text-only extraction misses critical PK/PD information often presented in tabular or graphical formats in protocols

#### Generalizability

Proof-of-concept is strong, but the system needs fine-tuning on larger, multi-modal datasets (text + tables) to be robust enough for production-level regulatory filing support.

**Figures & Tables**

- **Figure 1**: Schematic of the RAG system architecture showing the flow from Document Ingestion -> Vector Store -> LLM -> User Interface.
  - *Significance*: Visualizes the technical implementation of the compliance checking workflow.
- **Figure 3**: Screenshot of the PEARL (Protocol Evaluation and Review with LLM) interface.
  - *Significance*: Demonstrates the user experience and how the tool separates protocol upload from guidance upload.
- **Table 1**: Characteristics of the Approved and Withdrawn drug datasets used in the study.
  - *Significance*: Establishes the diversity of the test set, covering small molecules and biologics across various therapeutic areas.

---

**Code & Reproducibility Assessment**

The paper describes the use of open-source tools (LangChain, Streamlit, DeepEval) and provides prompt structures in Supplementary Data, but a direct code repository link is not provided in the main text.

---

**Supplementary Materials**

Supplementary materials include detailed prompt structures, the full text of the RAG outputs for all drugs, and the specific text of the FDA guidance documents used for the knowledge base.

---

**Future Directions**

The authors suggest extending the system to handle multimodal data (graphs/tables) to better capture PK/PD results. Future work should also explore using RAG for trial design comparison (endpoints, inclusion criteria) across competitor trials and integrating these tools into the FDA's own AI initiatives like ELSA.

---

**Expert Commentary**

This paper represents a significant step in 'Regulatory Pharmacometrics.' While much AI focus has been on data analysis, this highlights the efficiency gains available in document processing. The finding that RAG provides more critical, actionable feedback than raw LLMs is crucial—it suggests that for regulatory tasks, 'context is king.' However, the inability to read tables/graphs is a major bottleneck for pharmacometrics, where key parameters are rarely just in the text. The future lies in multi-modal RAGs that can 'see' the PK parameter table and cross-reference it with the text.

---

**Bottom Line**

RAG-based AI systems are a viable technology for automating the regulatory compliance review of drug labels and clinical protocols. By grounding LLMs in specific FDA guidance, these systems

reduce hallucinations and provide structured, actionable critiques that outperform standard chatbots. Pharmacometricians should view these tools as emerging 'regulatory assistants' that can streamline the non-quantitative aspects of drug development.
